

Research Methods Field Notes

Coastal water quality pilot, synthetic teaching packet

Key question: Can a simple field protocol detect a short-lived turbidity spike after rainfall?

Protocol

- collect three surface samples at each site
- record air temperature, water temperature, and turbidity
- rinse the probe before every site change
- flag readings that differ from the site median by more than 15 percent

Site	Time	Turbidity NTU	Note
A	08:10	2.1	baseline
B	08:40	8.4	after rainfall
C	09:15	3.0	downstream recovery

Equation note

Mean turbidity = $(x_A + x_B + x_C) / 3$. Use this as a quick screening value, not as a substitute for reviewing each reading.

Image-Like Field Note

This page deliberately includes a raster note block so the exported Markdown has something the user should review against the source.

Figure 1. Raster note block from the field notebook. Check numeric readings after export.

Margin note

The image region should be checked after export. If OCR misreads a number, correct the Markdown before using it.

Review Prompts

- Which step in the protocol is most likely to introduce measurement error?
- Which site should be resampled if time allows?
- What limitation should appear in a short methods note?

References

Synthetic protocol note, version 1. Local review before reuse.

Final reminder

Do not treat extracted Markdown as verified data until the source and output have been compared.
